# EUPHAUSIACEA AND MYSIDACEA.

---

BY WALTER M. TATTERSALL, D.Sc., KEEPER OF THE MANCHESTER MUSEUM.

---

With Plate XVIII.

THROUGH the courtesy of Professor Haswell I have had the opportunity of examining the Crustacea belonging to the old order Schizopoda, collected during the course of the Australian Antarctic Expedition under the leadership of Sir Douglas Mawson.

The expedition explored that part of the Antarctic continent and adjacent ocean which lies between Kaiser Wilhelm II Land (the head-quarters of the German Expedition) and Victoria Land (the head-quarters of the British Expeditions), *i.e.*, between 90° E. long. and 170° E. long.

Of the numerous recent expeditions to the Antarctic, the French, Belgian, Swedish, German, Scotch, and English have already published reports on the orders of Crustacea here dealt with, and as these expeditions between them cover the entire Antarctic Ocean, our knowledge of the Schizopodan Fauna of these waters is now considerable. It was, therefore, not to be expected that the present collection would be rich in novelties, and indeed such is the case. The collection is a small one, comprising four species of Euphausians, and two of Mysids. One species of Mysid is new to science, but it is not an Antarctic species, having been collected in the Auckland Islands. The other five species are well known Antarctic and Sub-Antarctic species which have been reported by all the recent South Polar Expeditions.

The new species belongs to a genus described in 1900 by Mr. G. M. Thomson, from specimens collected in New Zealand waters. Since that date it does not appear to have been met with. The discovery of a second species by the "Aurora," is, therefore, a matter of some interest.

I wish to express my thanks to Professor Haswell for his kindness in entrusting this collection to me for examination and report.

## ORDER EUPHAUSIACEA.

*Family* EUPHAUSIIDÆ.*Genus* EUPHAUSIA Dana.

## EUPHAUSIA SUPERBA Dana.

*E. superba* Tattersall, 1908. (With full synonymy.)

*E. superba* Hansen, 1913.

*Localities*—

3rd January, 1914	} In surface tow-nettings taken during the cruise along the pack-ice westward from Adelie Land to Davis Sea. Numerous specimens up to 50 mm.
4th January, 1914	
5th January, 1914	
6th January, 1914	
14th January, 1914	

From the stomach of a Weddell seal and an Emperor penguin, Adelie Land, January, 1913.

From the stomach of *Trematomus lœnnbergii* Regan, No. 10, and *Prionodraco* sp., No. 62.

*Euphausia superba* is known to form a large part of the food of the crab-eating seal, *Lobodon carcinophaga* and of the Antarctic penguins, but I am not aware that it has been previously recorded from Weddell's Sea, *Leptonychotes weddelli*, or from any of the Antarctic fishes.

## EUPHAUSIA CRYSTALLOROPHIAS Holt and Tattersall.

*E. crystallorophias* Holt and Tattersall, 1906.

*E. crystallorophias* Tattersall, 1908.

*E. crystallorophias* Hansen, 1908.

*Locality.*

From the stomach of *Trematomus eulepidotus* Regan, No. 18, several specimens in a somewhat fragmentary condition. This species comes very near to *Euphausia frigida* Hansen, but may be recognised by the much longer rostrum and by the absence of lobes on the distal extremity of the basal joint of the antennular peduncle. The copulatory organs on the first pleopods of the male are very similar indeed to those described by Hansen for his species.

*E. crystallorophias* was captured in enormous numbers by the "Discovery," from holes made in the ice at Winter Quarters on Victoria Land, to the east of the area explored by the "Aurora." It has only been recorded by one other South Pole Expedition, the "Belgica," having captured three young specimens in about lat. 70° S., long. 82° 37' W.

*Genus* THYSANOESSA Brandt.

## THYSANOESSA GREGARIA G. O. Sars. ?

*T. gregaria* Hansen, 1911.

*T. gregaria* Hansen, 1913.

*Locality.*

Off Macquarie Island, 18–19th June, 1912, 26 m. tow-net, 8 p.m.–8 a.m., sixty-three specimens, 4–10 mm.

These specimens are all immature and very fragmentary. Only two specimens retain their long legs. In one of these specimens, 6.5 mm. in length, the fifth joint of the long leg is twice as long as the sixth and seventh joints combined. In the other specimen, 10 mm. long, the fifth joint is one and three quarter times as long as the combined sixth and seventh joints. In both specimens the combined length of the fourth and fifth segments of the abdomen is one and a quarter times the length of the sixth segment. Small specimens of *Thysanoessa* are extremely difficult to determine, and Hansen, who has studied this genus exhaustively admits that small *T. gregaria* are difficult to separate from small *T. macrura*. In the present collection there is one specimen of *T. macrura*, 10 mm. long, that is, about the size of the largest specimen of those I refer to, *T. gregaria*. It still retains its long legs, and, in these limbs, the fifth joint is 2.6 times as long as the combined sixth and seventh. The fourth and fifth segments of the abdomen are together equal to the sixth. These proportions differ considerably from those in the specimens I have referred to *T. gregaria*.

In the figures illustrating Sars' account of this species in the "Challenger" Report, taken presumably from specimens 18 mm. long, the fifth joint of the first leg is 1.77 times as long as the combined sixth and seventh joints, and the combined fourth and fifth segments of the abdomen are 1.2 times as long as the sixth. These proportions are in close agreement with those given above.

I do not think the present specimens can be *T. vicina* Hansen, for in all that still retain the upper flagellum of the antennules, it is shorter than the distal two joints of the peduncle, whereas in *T. vicina* it is longer. Moreover, in *T. vicina* the proportions of the abdominal segments is about the same as in *T. macrura*.

I think these specimens are correctly referred to *T. gregaria*, but, owing to their poor state of preservation, the identification must remain doubtful.

## THYSANOESSA MACRURA G. O. Sars.

*T. macrura* Tattersall, 1908.

*T. macrura* Hansen, 1911.

*T. macrura* Hansen, 1913.

*Localities.*

4th January, 1914. Tow-net at 5 fathoms, twenty-two specimens, 7-12 mm.

10th January, 1914. Tow-net at 100 fathoms, 2 ♀ and 1 ♂, 22-25 mm.

Both these tow-nettings were taken during the cruise along the pack-ice westward from Adelie Land to Davis' Sea.

21st January, 1914. Lat.  $66^{\circ} 47' 21''$  S., long.  $93^{\circ} 14'$  E., off Drygalski Island, tow-net at 20 fathoms, twenty-eight specimens, 7-16 mm.

Nearly all these specimens are badly damaged, and very few retain any of the thoracic limbs. Their identity is, therefore, a matter of some doubt. In the gatherings made on 10th January, 1914, and 21st January, 1914, there are adult males and their copulatory organs on the first pair of pleopods agree with those figured by Hansen (1913) as characteristic of this species. For the remainder, I have relied on the length of the upper flagellum of the antennules (in such specimens as still retain them), which is shorter than the combined length of the last two joints of the antennular peduncle, to separate them from *T. vicina*, and the proportionate length of the last segment of the abdomen to distinguish them from *T. gregaria*.

From measurements which I have made on fifty specimens, I find that, taking the length of the last abdominal segment as unity, the combined length of the fourth and fifth segments varies between .94 and 1.06.

In the gathering made on 4th January, 1914, I found one specimen, 10 mm. long, which still retained its long legs. In this specimen, the fifth joint of the long legs was 2.6 times as long as the combined sixth and seventh joints. In the same bottle there were nine loose legs of the first pair, and measurements made on these show that the fifth segment varies from 2.12 to 2.64 times as long as the combined sixth and seventh joints. This variation, however, is one of age. In the smaller limbs the fifth joint is relatively shorter than in the larger limbs, and this joint evidently becomes more elongated as the animal grows. In adult *T. vicina*, about 12 mm. in length, the fifth joint of the long leg is about twice as long as the combined sixth and seventh joints (*vide* Hansen, 1913, plate VI, fig. 2c.). In *T. macrura*, 10 mm. the proportion is already 2.6 to 1 while, in a loose leg, which to judge from its size belonged to a specimen about 7 mm. long, the proportion is already 2.12 to 1, *i.e.*, of the proportions of adult *T. vicina*. In fully grown *T. macrura* the fifth joint of the long leg is from 3.5 to 3.8 times as long as the combined sixth and seventh joints (*vide* Tattersall, 1908, plate III, fig. 8 and Hansen, 1913, plate VI, fig. 3c.). Consideration of these measurements has led me to refer all the present specimens to *T. macrura*, and this identification is supported by the form of the first pleopods of such adult males as there happen to be present.

## ORDER MYSIDACEA.

## SUB-ORDER MYSIDA.

*Family* MYSIDAE.*Sub-family* MYSINAE.*Genus* TENAGOMYSIS *G. M. Thomson.**Tenagomysis* *G. M. Thomson, 1900.*

This genus was instituted for a species, *T. novæ-zealandiæ*, found not uncommonly on the coasts of New Zealand, but I am not aware of any subsequent records since Thomson's paper, nor of any further described species which may be referred to the genus. The species described below is very readily distinguished from the type form, though clearly referable to this genus. In view of the recent advances of our knowledge of the Mysidæ it seems desirable to re-define the genus, and to indicate its place in the family.

The genus *Tenagomysis* may be defined as follows:—Carapace rather short, leaving at least the last two thoracic segments entirely exposed, produced anteriorly into a moderate frontal plate; eyes moderately large and well developed, pigment black; antennal scale lanceolate in shape, setose all round, with a distal transverse suture near the apex; thoracic legs slender, sixth joint divided by vertical articulations into numerous subjoints (four in the type, ten to fourteen in the new species described below), seventh joint (dactylus) feeble; pleopods of the male essentially as in the genus *Leptomysis*, first pair with the endopod quite short and unjointed with the usual lateral plate, exopod long and multiarticulate; second, third, fourth, and fifth pleopods of the male well developed and biramous, the rami except in the fourth pair, subequal and without any specially modified armature; the exopod of the fourth pair longer than the endopod, with a strong spiniform and barbed seta on the outer side of each of the antepenultimate and penultimate joints; telson varying in length, its margins armed with spines, cleft at the apex, the cleft armed with closely-set pectinations, and the centre of the cleft bearing two plumose setæ; uropods rather long and slender, the exopod without a distal suture and without spines, the endopod with spines along the inner margins; female with three pairs of marsupial lamellæ (*vide* *G. M. Thomson*); type, *Tenagomysis novæ-zealandiæ* Thomson.

Hansen (1910) has divided the Mysidæ into six sub-families and one of these sub-families, the Mysinæ, into which *Tenagomysis* falls, is further divided up into four tribes. In all its essential features *Tenagomysis* agrees with Hansen's definition of the tribe Leptomysini, but its inclusion therein will necessitate a slight modification of the characters assigned to the tribe. This is in the number of subjoints into which the tarsus of the thoracic legs is divided. Hansen's definition runs "Sixth joint of thoracic legs [tarsus] with two, rarely three, vertical articulations and no oblique articulation." The new species described below though otherwise clearly belonging to this genus has

from ten to fourteen vertical articulations on the sixth joint of the thoracic legs, a number which has so far only been met with among the Mysini. It is obvious, therefore, that this character cannot be used as a differentiating character of the various tribes of the sub-family.

Among the genera assigned by Hansen to the tribe Leptomysini, *Tenagomysis* approaches perhaps most closely to the genus *Leptomysis*, differing only in the form of the telson. The latter, indeed will serve to distinguish the genus from all its congeners. Its general form is strikingly like that found very frequently among the Mysini, especially such genera as *Macromysis* and *Schistomysis*, with the important difference that in the latter genera there are no plumose setæ in the centre of the clefts of the telson, whereas *Tenagomysis* possesses a pair in that position. These setæ are entirely absent in the genera of the Mysini, characteristic of the Erythropini, and present in *Mysideis* and *Mysidopsis* alone of the genera belonging to the Leptomysini. *Tenagomysis* thus presents small features characteristic of three of the tribes of the sub-family Mysinae.

TENAGOMYSIS TENUIPES *sp. nov.*

(Plate XVIII, figs. 1-7.)

*Locality*.—Carnley Harbour, Auckland Islands, 24th June, 1912, one adult ♂, 21 mm.

*Description*.—General form moderately slender; *carapace* having the anterior margin produced into a triangular rostral plate which extends for about one-third of the way along the basal joint of the antennules and is shorter than the eye; rostral plate (fig. 1) about three-fifths as long as broad at its base, apex obtusely pointed; last two segments of the thorax left completely uncovered by the carapace.

*Antennular peduncle* (fig. 1) rather elongate, about as long as the sixth segment of the pleon; basal joint about as long as the second and third combined; second joint very short; third joint with a prominent spine on the dorsal anterior margin between the bases of the flagella; latter very long and slender; the basal joint has a few setæ on the outer distal corner; male appendage well developed and densely hirsute.

*Antennal peduncle* (fig. 2) not as long as the basal joint of the antennular peduncle, second joint slightly longer than the third.

*Antennal scale* (fig. 2) exceedingly long and narrow, extending for one quarter of its length beyond the distal end of the antennular peduncle, eleven times as long as broad, narrowly lanceolate in shape, setose all the way round, distal joint exceedingly small but distinctly present; the basal joint from which both the scale and peduncle spring, bears on its lower surface two strong spines, an inner and an outer, under the base of the peduncle and scale respectively.

*Thoracic legs*.—The form of the endopods of the first and second thoracic limbs is shown on plate XVIII, figs. 3 and 4. They present no special points. The basal joint

of the exopod is freely acuminate at the outer distal corner, and the flagellum-like portion is composed of nine joints. The endopods of the remaining thoracic limbs (fig. 5) are long and slender, increasing in length from the third to the seventh limbs, the endopod of the eighth limb being much shorter than that of the seventh. The sixth joint is divided into nine subjoints in the third limb, the number increasing to fourteen in the seventh limb, the eighth limb having only ten. The dactylus is feebly developed and not claw-like. The basal joint of the endopods of the third to the eighth pair of thoracic limbs bears a well-developed epipodial process.

*Abdomen.*—With the sixth segment twice as long as the fifth; first pair of pleopods of the male with the endopod short and unjointed, and having the usual lateral lamella, exopod well developed and multiarticulate; second, third, and fifth pair of pleopods in the male, well developed, biramous, the rami approximately equal and not having any modified armature; fourth pair of pleopods in the male (fig. 6) well developed, biramous, the outer ramus nearly twice longer than the inner, and having on the outer distal corner of the antepenultimate and penultimate joints, a long strong spiniform seta barbed on the distal half of their margins; the basal joint of the exopod bears a short blunt process on its lower and inner surface.

*Telson* (fig. 7) longer than the sixth abdominal segment, dorsally channelled, and therefore ventrally keeled, two and a half times as long as broad at its base, margins armed throughout their entire length by about thirty-six spines, the terminal spine of each margin rather stronger than the other spines; apex cleft, the cleft equal to about one-fifth of the total length of the telson and armed with closely set pectinations as well as with two plumose setæ at the centre, the setæ slightly longer than the cleft.

*Uropods* long and slender; inner plate one quarter longer than the telson, its inner margin armed with spines extending from the statocyst to the apex, the spines being closely set for the greater part of the margin but becoming more distantly placed and longer towards the apex, arranged more or less in series, sometimes as many as four in a series, but the serial arrangement is not regular nor obvious; the outer margin of the inner uropods bears in addition to the usual setæ a few scattered “kegelförmige” bristles; outer uropods one and a half times as long as the inner, rather slender and narrow in form.

*Length* of the type and only specimen, an adult male, 21 mm. The type has been deposited in the British Museum.

*T. tenuipes* is easily distinguished from the type and only other described species of the genus by the extreme length and tenuity of the thoracic limbs, and especially by the larger number of subjoints in the sixth joint of the endopods, by the longer and narrower antennal scale, by the longer telson and the larger number of spines arming its margins, and by the armature of the inner margin of the inner uropods. I have four undescribed species of the genus taken in New Zealand waters on the last expedition of the “Discovery.” They will be described in the Reports on that Expedition, but

they are all much smaller and more robust forms. The point to note here is that the genus is a fairly big one, and is characteristic of New Zealand waters, not having been met with in any other part of the waters of the globe.

*Genus ANTARCTOMYSIS Coutière.*

ANTARCTOMYSIS MAXIMA (*Hansen, M.S.*) *Holt and Tattersall.*

*Mysis maxima* Holt and Tattersall, 1906.

*Antarctomysis maxima* Coutière, 1906.

.. Hansen, 1908.

.. Tattersall, 1908.

.. Hansen, 1913.

*Localities.*

Station 7, 21st January, 1914; lat.  $66^{\circ} 47' 21''$  S., long.  $93^{\circ} 14'$  E.. off Drygalski Island, 60 fathoms, stones, 1 ♀, 34 mm.

Station 11, 31st January, 1914; lat.  $64^{\circ} 43' 47''$  S., long.  $97^{\circ} 25' 10''$  E., 358 fathoms. mud, 1 ♂, 55 mm.

Station 12, 31st January, 1914; lat.  $64^{\circ} 39' 19''$  S., long.  $97^{\circ} 19' 21''$  E., 110 fathoms, sand and stones, 5 ♂ and 17 ♀ up to 54 mm.

Both these last two stations are in Davis Sea, off Shackleton Shelf, near to the southern end of Termination Ice Tongue.

This species has been taken by all the recent Antarctic Expeditions and has a circumpolar distribution.

# CUMACEA AND PHYLLOCARIDA.

By W. T. CALMAN, D.Sc. (BRITISH MUSEUM, NATURAL HISTORY).

(Published by permission of the Trustees of the British Museum.)

(Plates XIX and XX)

THE collection dealt with in this report, although a very small one, is by no means devoid of interest. It comprises a new species of *Diastylis*, very distinct from any hitherto known from the Antarctic, and showing some resemblance to species inhabiting the North Pacific. Another *Diastylis* is referred to a species already known, of which it represents at least a very marked variation. The remaining Cumacea and the solitary *Nebalia* serve to fill in a very wide gap in the known distribution of the respective species. All the specimens were obtained near the Main Base of the expedition at Adelie Land. The following are particulars of the localities:—

Boat Harbour, Commonwealth Bay. Dredging, 5 fathoms. 1st June, 1912.  
*Nebalia longicornis*.

Station I. Lat.  $66^{\circ} 50' S.$ , Long.  $142^{\circ} 6' E.$ ; 358 fathoms. 26th December, 1913.  
*Cyclaspis gigas*.

Station II. Lat.  $66^{\circ} 55' S.$ , Long.  $145^{\circ} 21' E.$ ; 318 fathoms. 28th December, 1913.  
*Cyclaspis gigas*, *Diastylis Mawsoni*, *D. Helleri*.

## CUMACEA.

### CYCLASPIS GIGAS *Zimmer*.

*Cyclaspis gigas* Zimmer, Zool. Anz. XXXI, 1907, p. 367; id. Deutsche Südpolar Exped. XIV, Zool. vi, 1913, p. 441, pl. i, figs 1–3, text-figs. 1 and 2; Stebbing, Das Tierreich, Cumacea, 1913, p. 38; Calman, Brit. Antarctic ("Terra Nova") Exped. Zool. III, No. 5, 1917, p. 146.

*Occurrence*.—Stat. I, 1 ♀; Stat. II, 3 ♀.

*Remarks*.—The ovigerous female described by Zimmer was only 15 mm. in length, but an ovigerous specimen in the present collection is 20 mm. long, and some of the immature specimens exceed 18 mm. Nevertheless the agreement with Zimmer's

description and figures is very close, almost the only noteworthy discrepancy being that the endopod of the uropods bears on its inner edge a series of spines, up to nine in number, of which only the distal one persists in the specimen figured by Zimmer. The elevated portions of the surface of the carapace are rugose. As in the specimen recorded from the "Terra Nova" Expedition I can find no trace of corneal lenses on the ocular lobe.

Zimmer has figured a young specimen (8 mm. long) smaller than the holotype of Hansen's *C. glacialis*, but agreeing with the adult in the sculpturing of the carapace. None of the specimens that I have examined show any marked difference in this character. It seems not impossible, however, that a re-examination of Hansen's type would show some trace of the separation of "Höcker 2" from "Höcker 3" (in Zimmer's terminology), which separation is, at present, the only character available for distinguishing *C. gigas* from *C. glacialis*.

*Distribution*.—Lat.  $66^{\circ} 2' S.$ , Long.  $89^{\circ} 38' E.$ ; 385 metres ("Gauss"). Lat.  $77^{\circ} 46' S.$ , Long.  $166^{\circ} 8' E.$ ; 300 fathoms ("Terra Nova").

DIASTYLIS MAWSONI, *sp.n.*

(Plate XIX.)

*Occurrence*.—Stat. II, 3 ♀.

*Description*.—Immature female; total length, 18 mm. (An ovigerous female measures 16 mm.)

Carapace inflated, about one-third of total length, its height about two-thirds and its width about three-fourths of its length. Dorsal surface strongly vaulted in its posterior third, flattened and sloping downwards anteriorly. Surface marked with ridges which, in places, pass into an irregular reticulation, partly filling up the spaces between the main ridges. The strongly convex posterior part of the dorsal surface has two very prominent longitudinal ridges converging forwards, between which is a deep depression. From these, three oblique ridges pass downwards and forwards on the side of the carapace, the most anterior defining the flattened area of the dorsal surface. The third ridge is less regular in its course than the first and second, and behind it are some irregular reticulations which partly unite to outline a fourth oblique ridge. The lower ends of the first and second oblique ridges join with a somewhat irregular horizontal ridge, which runs forward to form a lateral keel on the pseudorostrum. A second horizontal ridge between the first and the lower margin of the carapace also runs a zigzag course, and is united with the first by a short vertical ridge. The flattened area of the dorsal surface is very rugose, and on it are a pair of longitudinal ridges close together, each giving off a forwardly-curved lateral branch. The pseudorostrum is short, obtusely pointed as seen from above, with its lateral margins pectinate. There

is no antennal notch and the anterior part of the lower margin of the carapace is pectinate. The ocular lobe is minute, without trace of an eye.

The pleural plates of the second free thoracic somite are small and rounded. The postero-lateral angles of the fifth somite are rounded.

The abdomen, including the telson, is longer by about one-fourth than the cephalo-thoracic region. The somites have a dorsal median ridge and paired dorso-lateral and ventro-lateral as well as some less marked transverse ridges.

The telson is a little more than twice as long as the last somite, the post-anal portion occupying more than one-third of its length. The basal portion has a flattened dorsal surface with dentate lateral margins. The narrower post-anal portion bears five or six pairs of rather long lateral spines.

The antennules have the last segment of the peduncle slender and twice as long as the preceding.

The third maxillipeds have the basis hardly widened distally, its distal outer corner slightly produced, the merus narrower than the ischium, and with two strong teeth on its ventral surface distally.

The first legs have the basis shorter than the distal segments together, the last three segments slender, successively increasing in length. The second legs have the carpus longer by about one-third than the two distal segments together. The posterior legs are stout. The third and fourth have each a minute exopod of two segments.

The peduncle of the uropods is a little longer than the telson, with rather slender spines on inner side. The endopod is longer than the exopod, with eight to twelve spines on inner edge, the first segment nearly as long as the second and third together.

*Remarks.*—According to the very artificial system of classification adopted by Stebbing in his revision of the Cumacea (Das Tierreich, 1913), this species would probably be placed in the genus *Adiastylis*, since the post-anal portion, being less than half of the total length of the telson, can hardly be termed "long." Of the species brought together in that genus the only one having any special resemblance to *D. Mawsoni* is *A. costatus* (Bonnier), which has oblique ridges on the carapace. It differs, however, in the arrangement of these ridges, in the absence of exopods on the third and fourth legs, and in a number of other characters. A close resemblance to *D. Mawsoni* can be traced within the restricted genus *Diastylis* (as used by Stebbing) in the group of species distinguished by the presence of vestigial exopods on the third and fourth legs of the female. This group includes five species, three of which are from the Alaskan area of the North Pacific, and the others from South Georgia and the Straits of Magellan. Two of the Alaskan species, *D. Dalli* and *D. bidentata*, resemble *D. Mawsoni* further in the general pattern of the obliquely ridged carapace. In view of the well-known affinity of certain elements of the North Pacific fauna with that of the sub-antarctic

region, it is possible that this resemblance may have some significance. It is obviously undesirable, however, to attempt any large deductions from the more or less trivial indications of relationship between individual species in a genus so large and so widely distributed as *Diastylis*; and it is doubly undesirable in the case of inconspicuous organisms that have been so little collected, except in European seas, as have the Cumacea.

*DIASTYLIS HELLERI* Zimmer.

(Plate XX.)

*D. helleri*, Zimmer, Zool. Anz. XXXI, 1907, p. 221; id. Wiss. Ergeb. Schwed. Südpolar Exped. VI, Lief. 3, 1909, p. 15, pl. vi, figs. 84-96; Calman, Deuxième Expéd. Antarct. Française, Cumacés, 1917, p. 1.

*Holostylis Helleri*, Stebbing, Das Tierreich, Cumacea, 1913, p. 140.

*Occurrence*.—Stat. II. 1 ♀ (immature).

*Remarks*.—The single specimen (which is much damaged) differs considerably in appearance from Zimmer's description and figures, and from a syntype of his species in the Museum collection. It might indeed have been regarded, without much hesitation, as representing a distinct species characterised by the nodular excrescences on the carapace, were it not that certain specimens obtained on the voyage of the "Nimrod" and presented to the Museum by Sir Ernest Shackleton stand almost exactly midway, in respect of this character, between Sir Douglas Mawson's specimen and those described by Zimmer. The "Nimrod" specimens differ from that now recorded in having the surface of the carapace much more spinous, but on the other hand they agree with it and differ from Zimmer's syntype in having the pseudorostrum longer than the antennule, and the basal portion of the telson somewhat longer relatively to the post-anal portion. The single specimen which I have recorded from the second French Antarctic Expedition \* is not now at hand for comparison, but according to my notes it agreed very closely with the "Nimrod" specimens.

In describing this species, Zimmer called attention to its resemblance to the Arctic *D. spinulosa* Heller. It is, therefore, of special interest to find it presenting a series of variations parallel to those that, according to Hansen, link *D. spinulosa* with *D. nodosa* Sars.

Stebbing has removed this species to a new genus, *Holostylis*, which he makes the type of a new family Holostylidæ, having as its sole distinguishing character the unsegmented endopod of the uropods.

*Distribution*.—South Georgia, 12-75 metres (Swedish S. Pole Exp.). Lat. 64° 49' 35" S., Long. 63° 29' 4" W.; 70 metres ("Pourquoi Pas?"). Cape Royds, 7-50 fathoms ("Nimrod").

---

\* The text of my note on this species in the Report of the French Expedition has apparently suffered from some accident now inexplicable. I must disclaim responsibility for the statement that Dr. Zimmer himself collected the species at South Georgia and the implication that he described the specimens obtained by the "Nimrod."

## PHYLLOCARIDA.

NEBALIA LONGICORNIS *G. M. Thomson.*

*N. longicornis* G. M. Thomson, Ann. Mag. Nat. Hist. (5) IV, 1879, p. 418, pl. xix, figs. 7-9; Thiele, Wiss. Ergebn. D. Tiefsee Exp. "Valdivia" VIII, 1904, p. 9, figs. on pl. iv; id. D. Südpolar Exp. 1901-1903, IX, 1905, p. 66, pl. ii, figs. 14-17; id. National Antarctic ("Discovery") Exp. 1901-1904. Nat. Hist. III, 1907. Leptostraca p. 1, text-figs.; Calman, Brit. Antarctic ("Terra Nova") Exp. Zool. III. No. 5, 1917, p. 156.

*Occurrence.*—"Boat Harbour, Commonwealth Bay, 5 fathoms." 1 ♀.

*Remarks.*—The specimen is a female carrying eggs, and measures 6.0 mm. in length of the lateral wings of the carapace. The rostral plate has the proportion of length to breadth as 2.04:1; the ocular peduncle has a very prominent and pointed sensory tubercle; and the fourth segment of the antennule carries one spine and seven or eight setæ. The specimen therefore differs little from those already recorded from the Ross Sea area ("Discovery" and "Terra Nova") on the one hand and from Wilhelm Land ("Gauss") on the other, and, with them, would appear to conform to Thiele's definition of his subspecies *magellanica*. If this subspecies be maintained (cf. Calman, 1 c.), the present specimen may be adduced in evidence for its circumpolar distribution and for the comparative uniformity of its characters throughout its wide range.

## EXPLANATION OF PLATES.

## Plate XIX.

Fig. 1.—*Diastylis Mawsoni*, sp.n. Immature female, from the side.

Fig. 2.—*Diastylis Mawsoni*, sp.n. Anterior portion of body from above.

Fig. 3.—*Diastylis Mawsoni*, sp.n. Posterior somites of abdomen, with telson and uropod.

## Plate XX.

Fig. 4.—*Diastylis Helleri*, Zimmer. Anterior portion of body from the side. A. Syntype from South Georgia. B. Specimen from Cape Royds. C. Specimen obtained by Australasian Expedition (the outline of the carapace slightly restored).
